Synergy Labs

Mirai-Dyn Attack 2016

The image is a screenshot of a Twitter post. At the top left is the GitHub logo (a yellow robot head icon) and the handle '@github'. To the right is the GitHub logo and the word 'Follow'. Below the handle is a placeholder image icon (a white document with a question mark). The tweet text starts with 'We're mor' and ends with 'now and'. The middle section of the tweet is cut off by a large, bold, black message: 'This site can't be reached'. Below this message, it says 'twitter.com's server DNS address could not be found.' and 'Try running Network Diagnostics.' At the bottom of the tweet, the error code 'DNS_PROBE_FINISHED_NXDOMAIN' is visible. On the far left of the screenshot, there are standard Twitter interaction icons: a retweet button, a reply button, and a like button showing '47' and '38' respectively. The timestamp '12:49 PM - 21 Oct' is also visible.

We're mor
DNS provi

RETWEETS LIKES

47 38

12:49 PM - 21 Oct

This site can't be reached

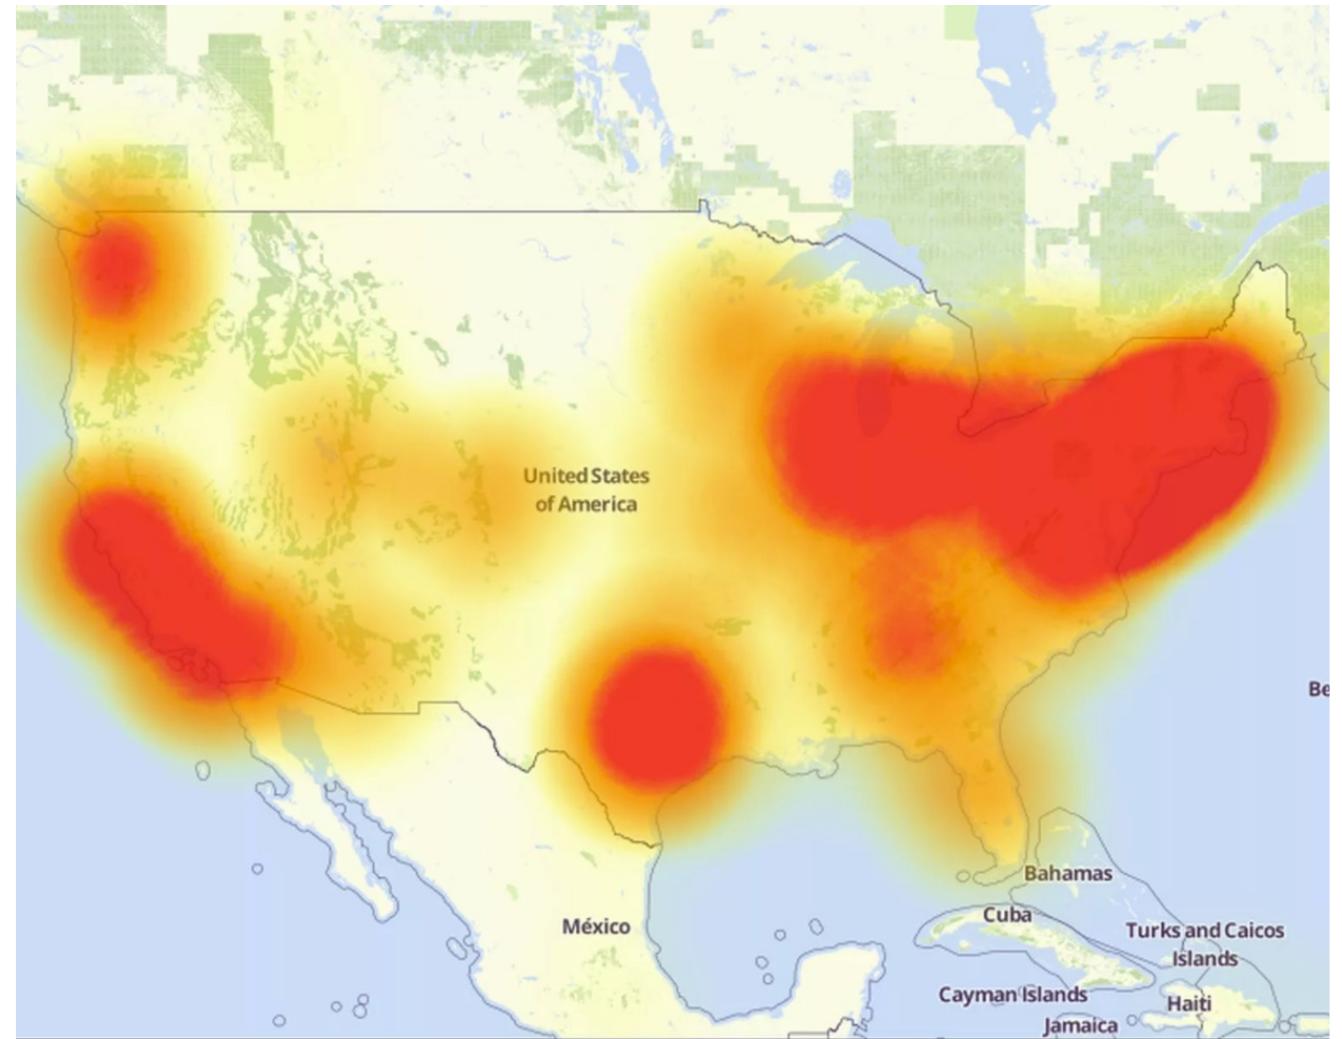

twitter.com's server DNS address could not be found.

Try running Network Diagnostics.

DNS_PROBE_FINISHED_NXDOMAIN

Mirai-Dyn Attack 2016

- 178,000 domains affected in total
- Tens of millions of users affected

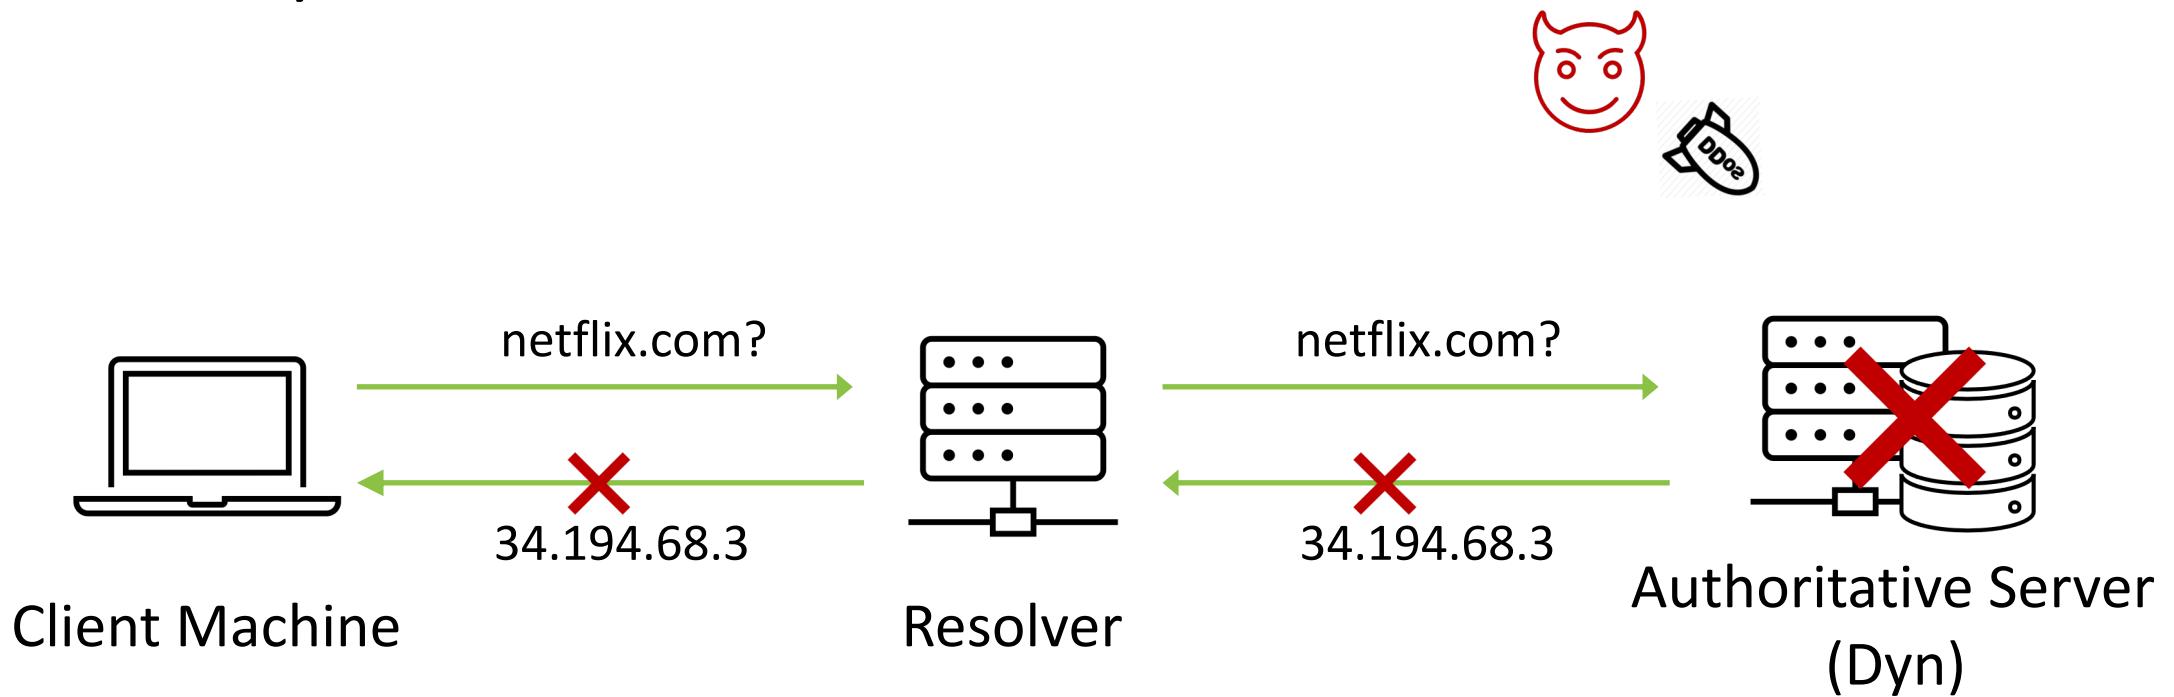

Mirai-Dyn Attack 2016

How was it possible to take all of these websites down?

Mirai-Dyn Attack 2016

Insight: Many websites relied on the same 3rd Party DNS provider (Dyn)

Motivating Questions for Our Work

- How prevalent are third party dependencies?

Methodology: Analysis on Alexa Top 100K websites

- Are there any indirect dependencies between websites and third-party providers?

Methodology: Analysis on inter-service dependencies

- How did the world change after the Dyn Incident?

Methodology: Comparison analysis on Alexa Top 100K sites in 2016 vs. 2020

Outline

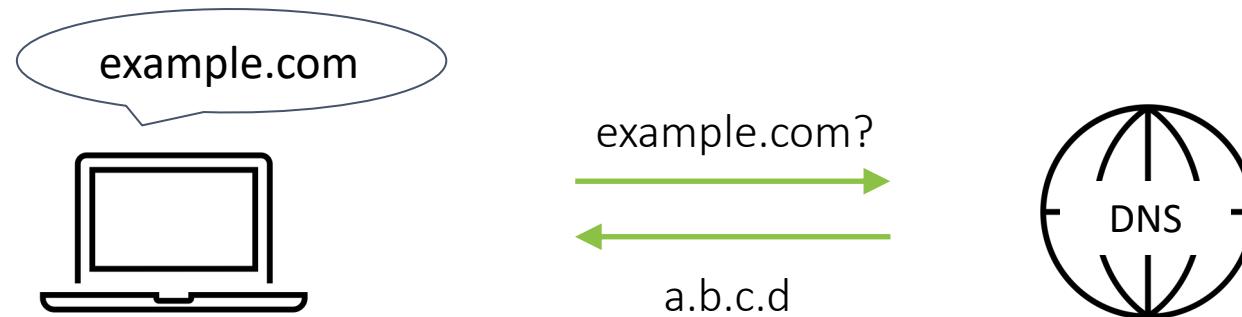

- Measurement Methodology
- Findings
- Recommendations
- Limitations
- Conclusion

Methodology: What services to measure?

Life Cycle of a Web Request

- Domain Name System (DNS)
For example, AWS DNS, Dyn.

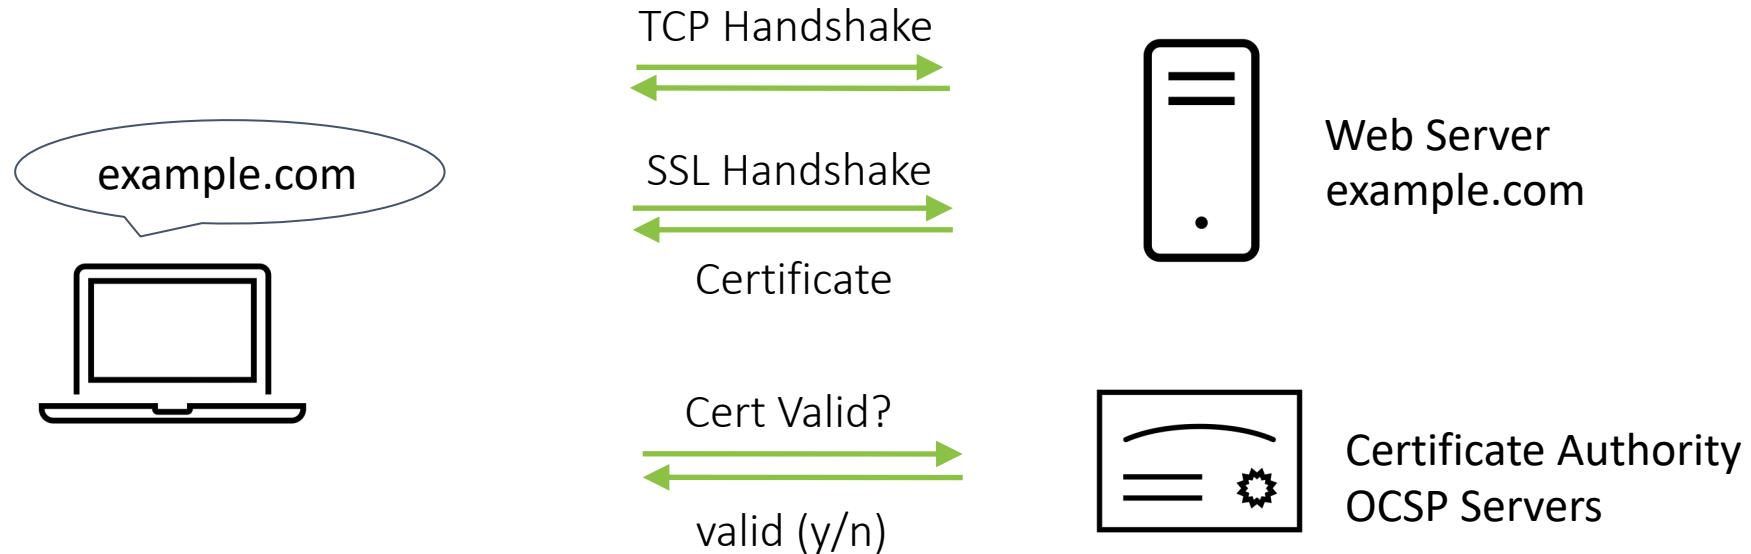

Methodology: What services to measure?

Life Cycle of a Web Request

- Domain Name System (DNS)
- Certificate Validation by CA

For example, DigiCert, Let's Encrypt.

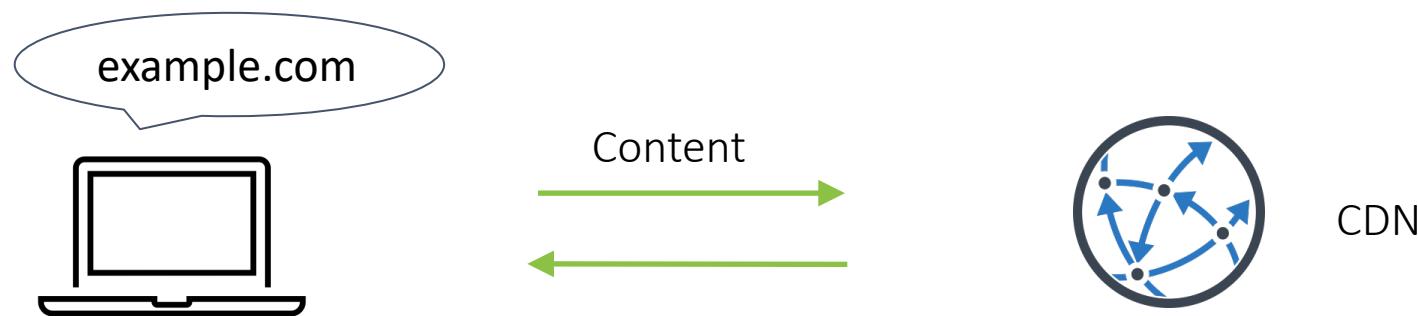

Methodology: What services to measure?

Life Cycle of a Web Request

- Domain Name System (DNS)
- Certificate Validation by CA
- Content Delivery Network (CDN)

For example, Akamai, CloudFlare

Methodology: What features to measure?

- Third Party Dependency
- Indirect Dependency
- Critical Dependency
 - No Redundancy in DNS and CDN provisioning
 - No OCSP stapling in certificate validation

Measuring 3rd party DNS dependency

- live.com *.azure-dns.com *.o365filtering.com } Q1. Are these third party or private? Q2. Do these belong to the same entity?

Identifying 3rd party DNS dependency: Prior efforts are error prone

- Using SLD + TLD Matching

<code>www.google.com</code>	<code>ns1.google.com</code>	Pvt	✓
<code>www.youtube.com</code>	<code>ns1.google.com</code>	3rd	✗

- Using SOA Records Matching

	NS	SOA	
<code>www.youtube.com</code>	<code>*.google.com</code>	<code>*.google.com</code>	Pvt
<code>www.twitter.com</code>	<code>*.dynect.net</code>	<code>*.dynect.net</code>	Pvt

Identifying 3rd party DNS dependency: Our Approach

For all *(website, NS)* pairs:

- SLD + TLD match
- $NS \in$ Subject Alternate Names (SAN) list

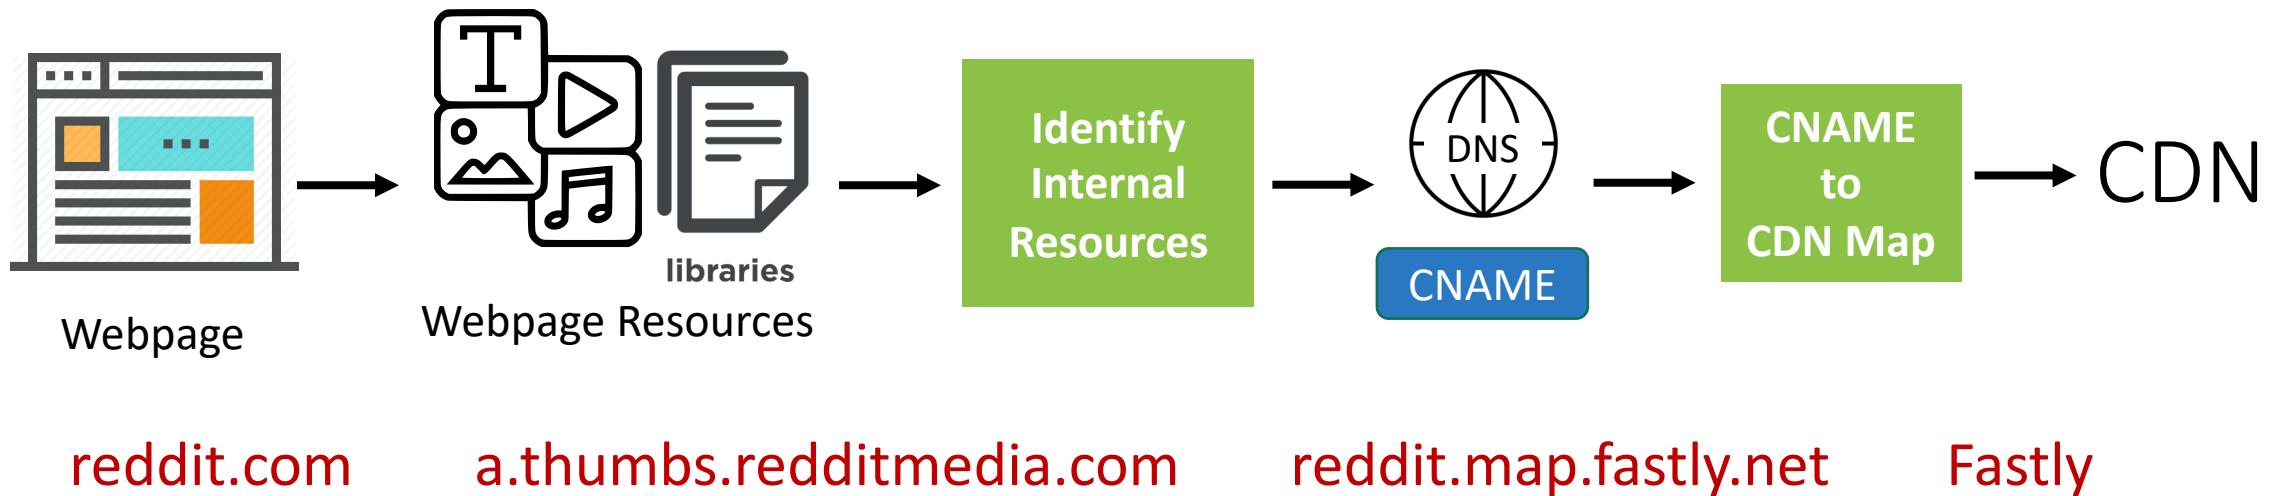

} Private

- SOA do no match
- $Concentration(NS) > 50$

} Third

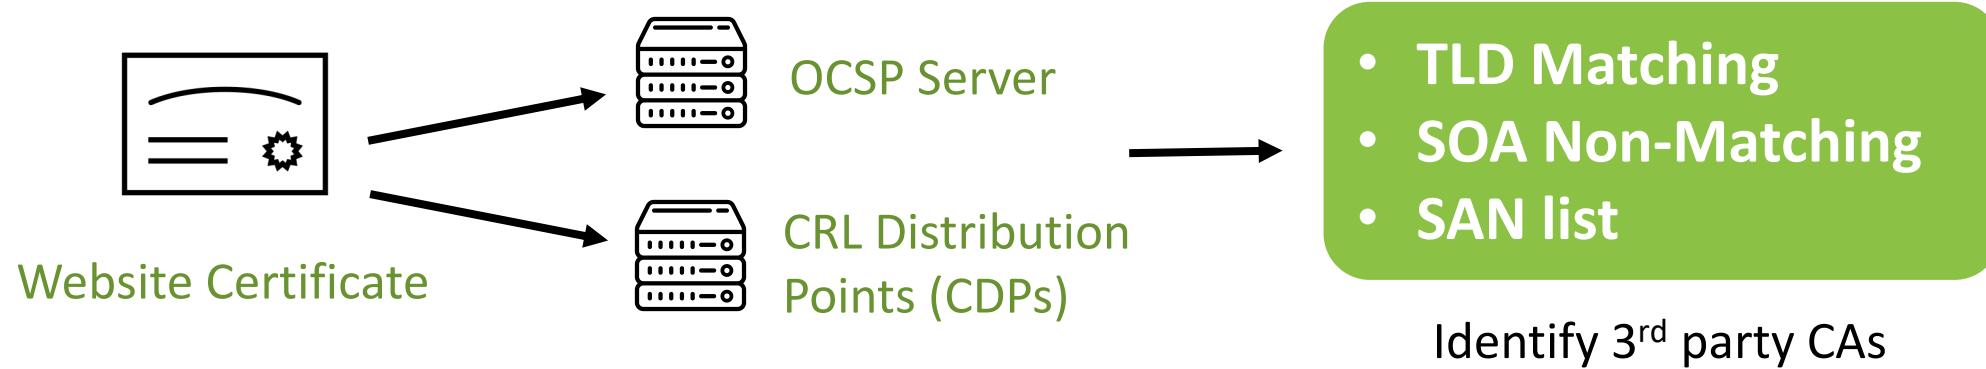

We identify 10K Third Party DNS Providers

Measuring 3rd Party CDN Dependency

- Use TLD, SOA, SAN of embedded links to identify internal resources
- Use TLD, SOA, SAN of CNAMEs used by CDNs to identify 3rd party CDNs
- We identify 86 Third party CDNs

Measuring 3rd party CA dependency

- We identify 59 third party CAs

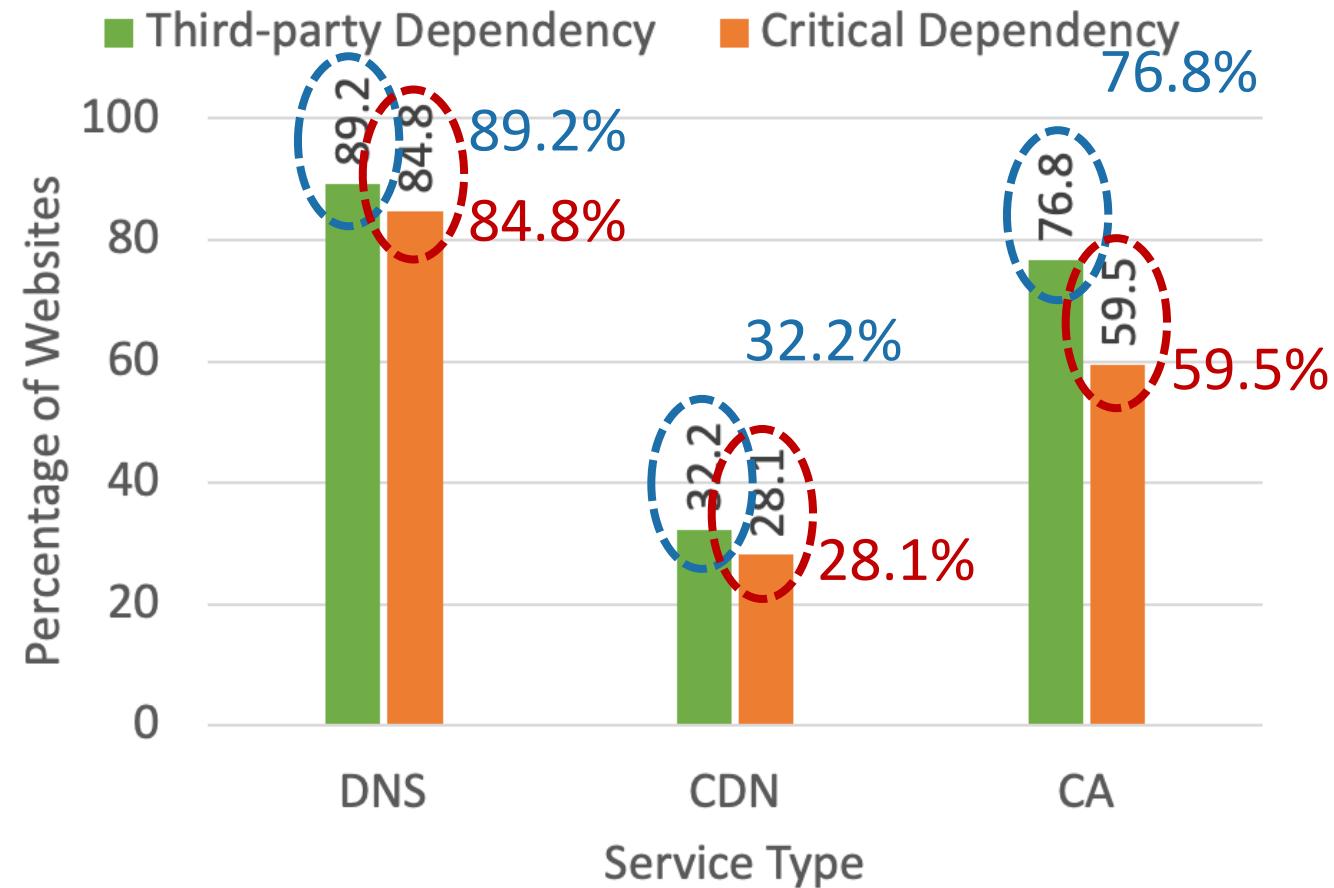

Outline

- Measurement Methodology
- Findings
- Recommendations
- Limitations
- Conclusion

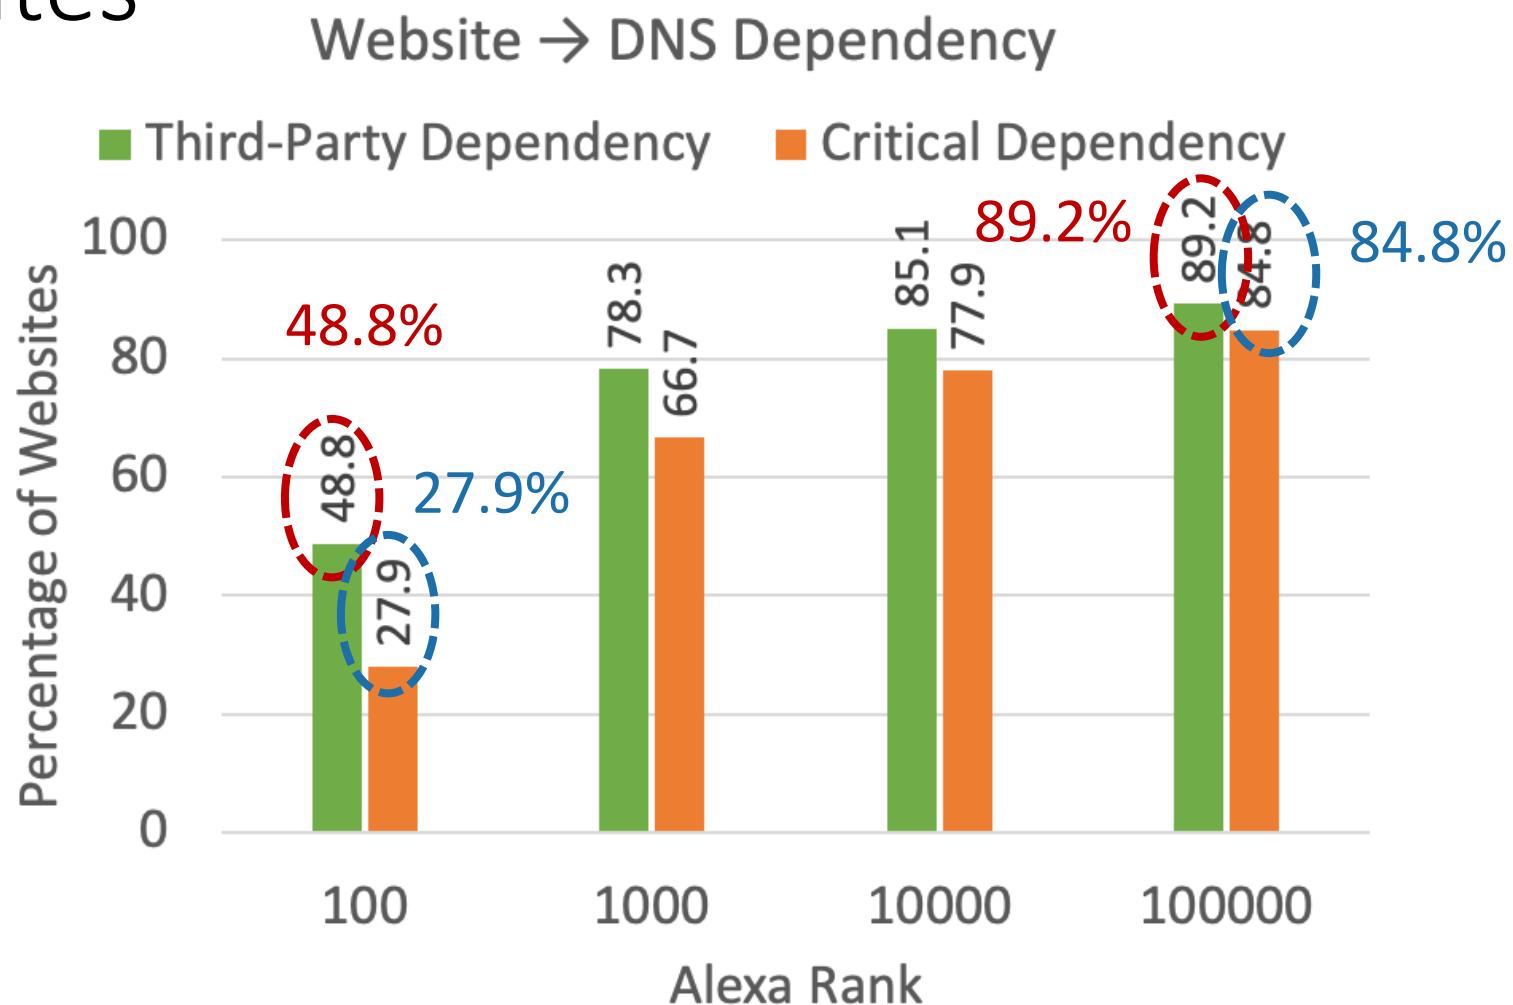

Q1: How prevalent are third-party dependencies?

Third-Party Dependencies are Highly Prevalent

89% of the top-100K websites critically depend on third-party DNS, CDN, or CA providers.

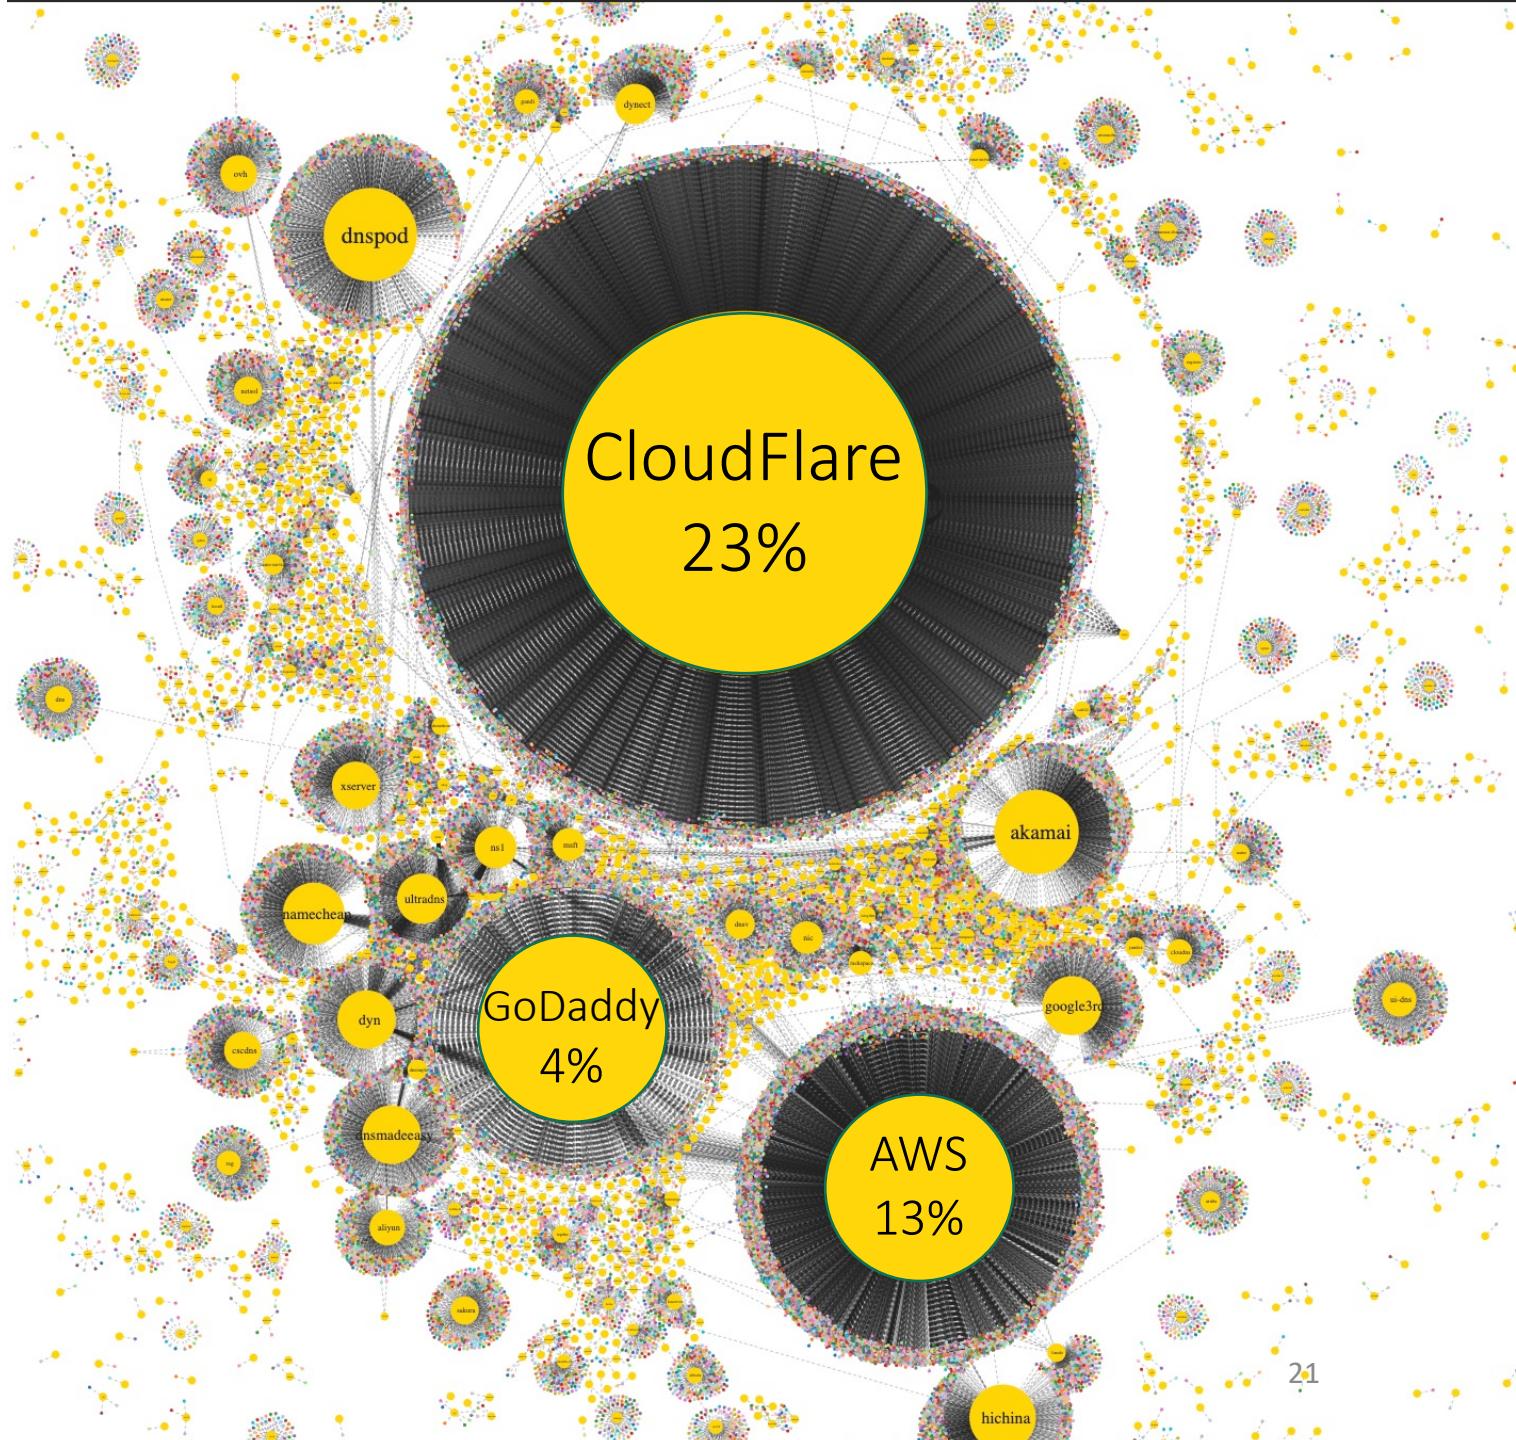

Third-Party Dependencies Higher for Less Popular Websites

Popular websites care more about availability.

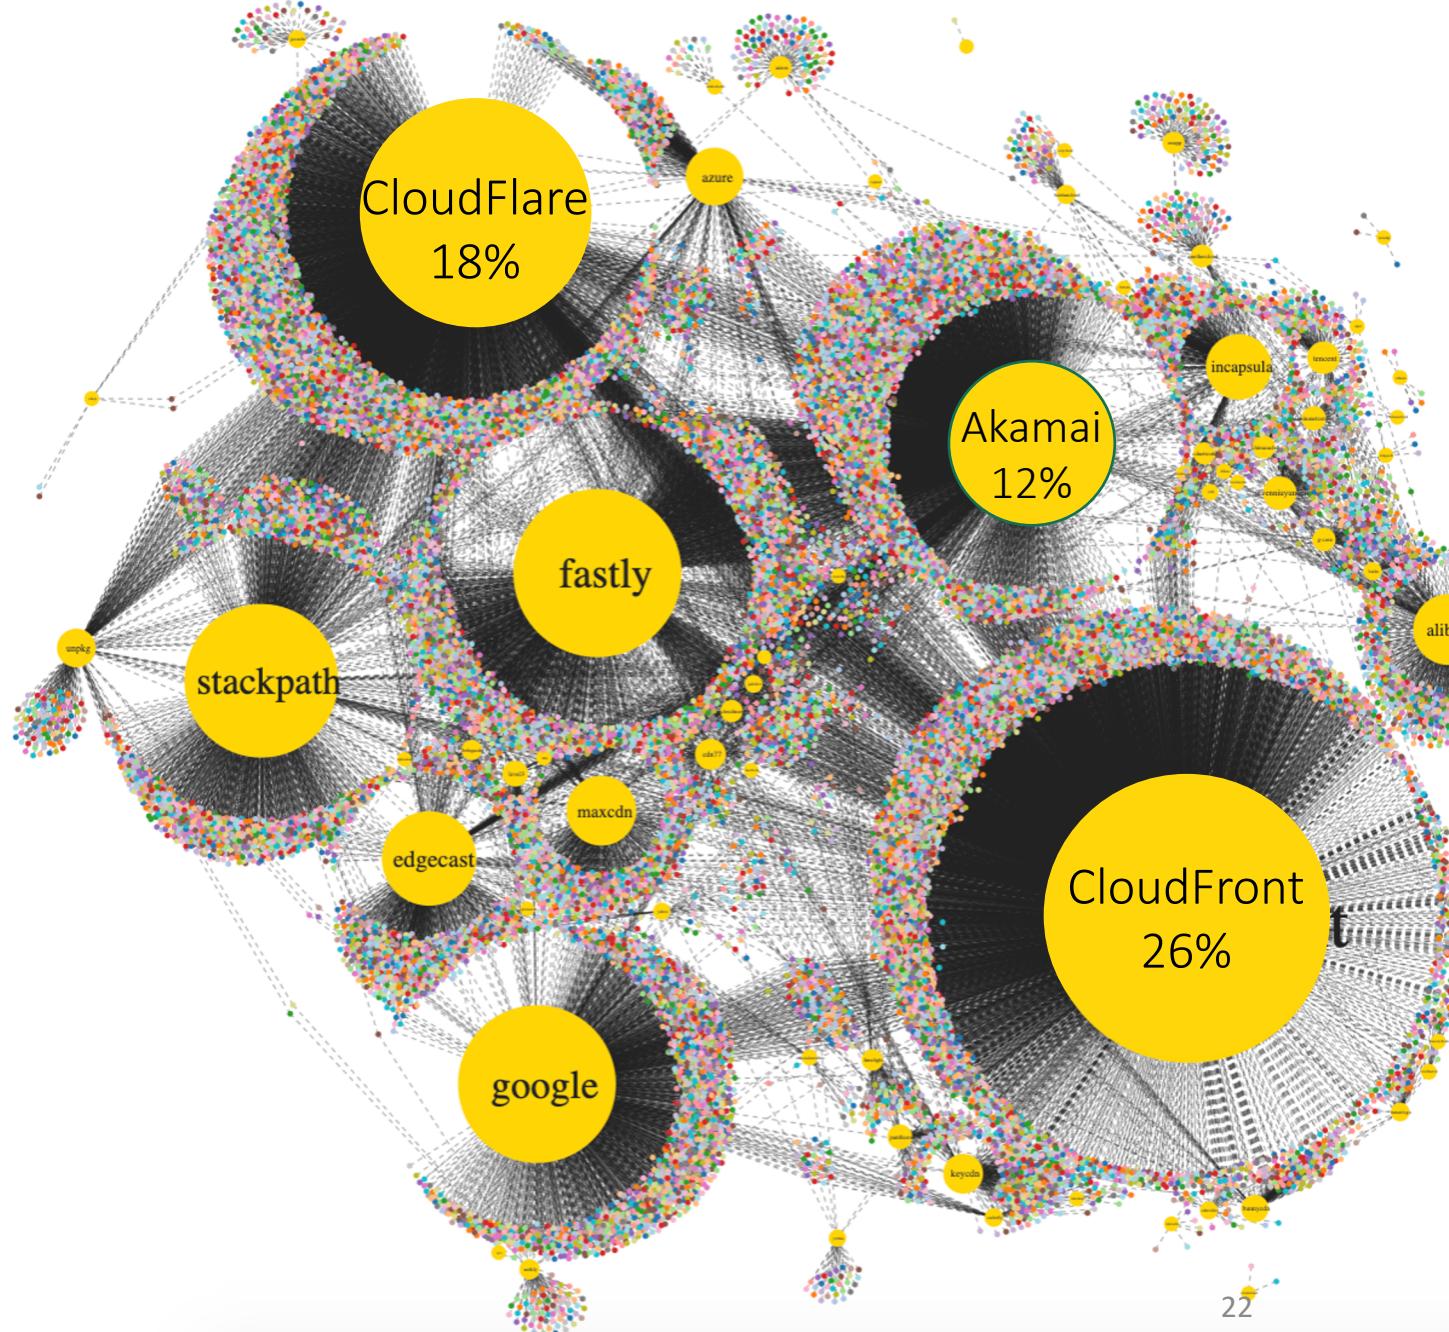

Concentration of DNS Providers

3 (out of 10K) DNS providers critically serve ~40% of the top-100K websites

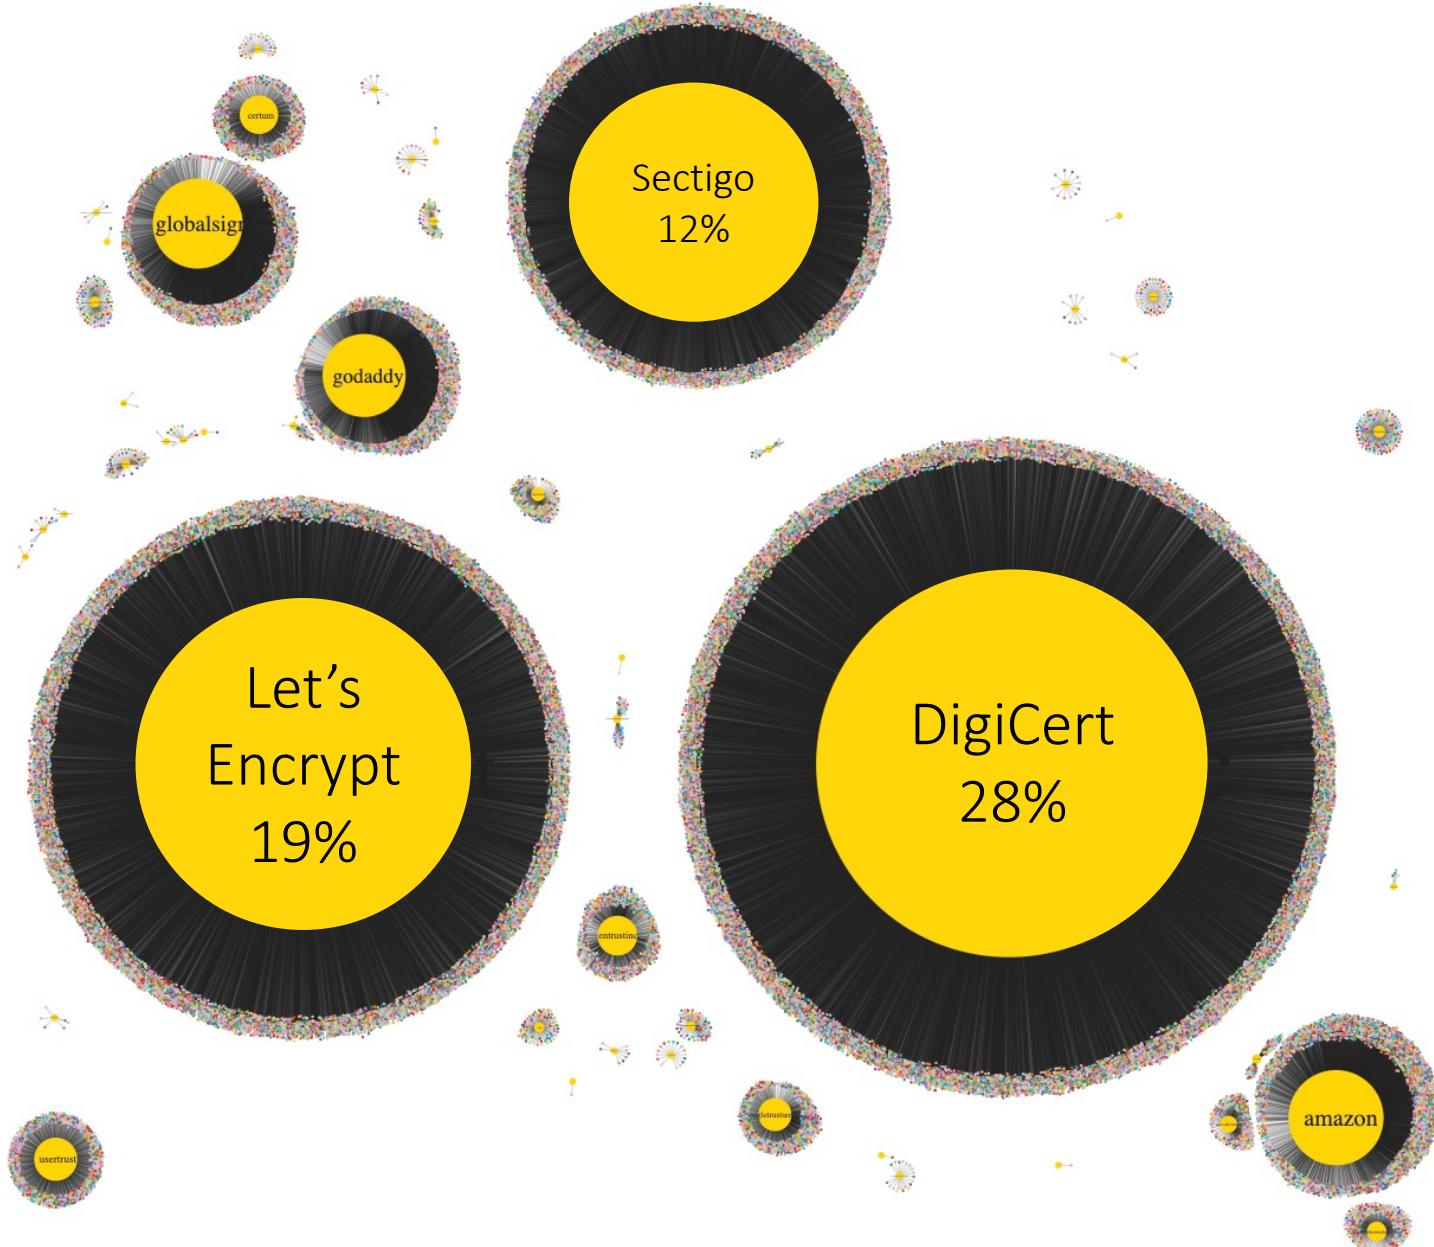

Concentration of CDN Providers

3 (out of 86) CDN providers
critically serve ~60% of the
top-100K websites using CDN

Concentration of CA Providers

3 (out of 59) CAs critically serve ~60% of the top-100K websites that support HTTPS

Takeaway

- Third party critical dependencies are highly prevalent.
- Third party services are highly concentrated.

Implications:

- 89% of the websites are vulnerable to Dyn like incidents
- A single third-party service provider can affect ~25% of the top 100K websites

Q2: Are there any indirect dependencies between websites and their third-party providers?

Inter-Service Third-Party Dependency

48%

CA → DNS

36%

CA → CDN

36%

CDN → DNS

Third-party dependencies are also prevalent among service providers

Inter-Service Critical Dependencies

31%

CA → DNS

36%

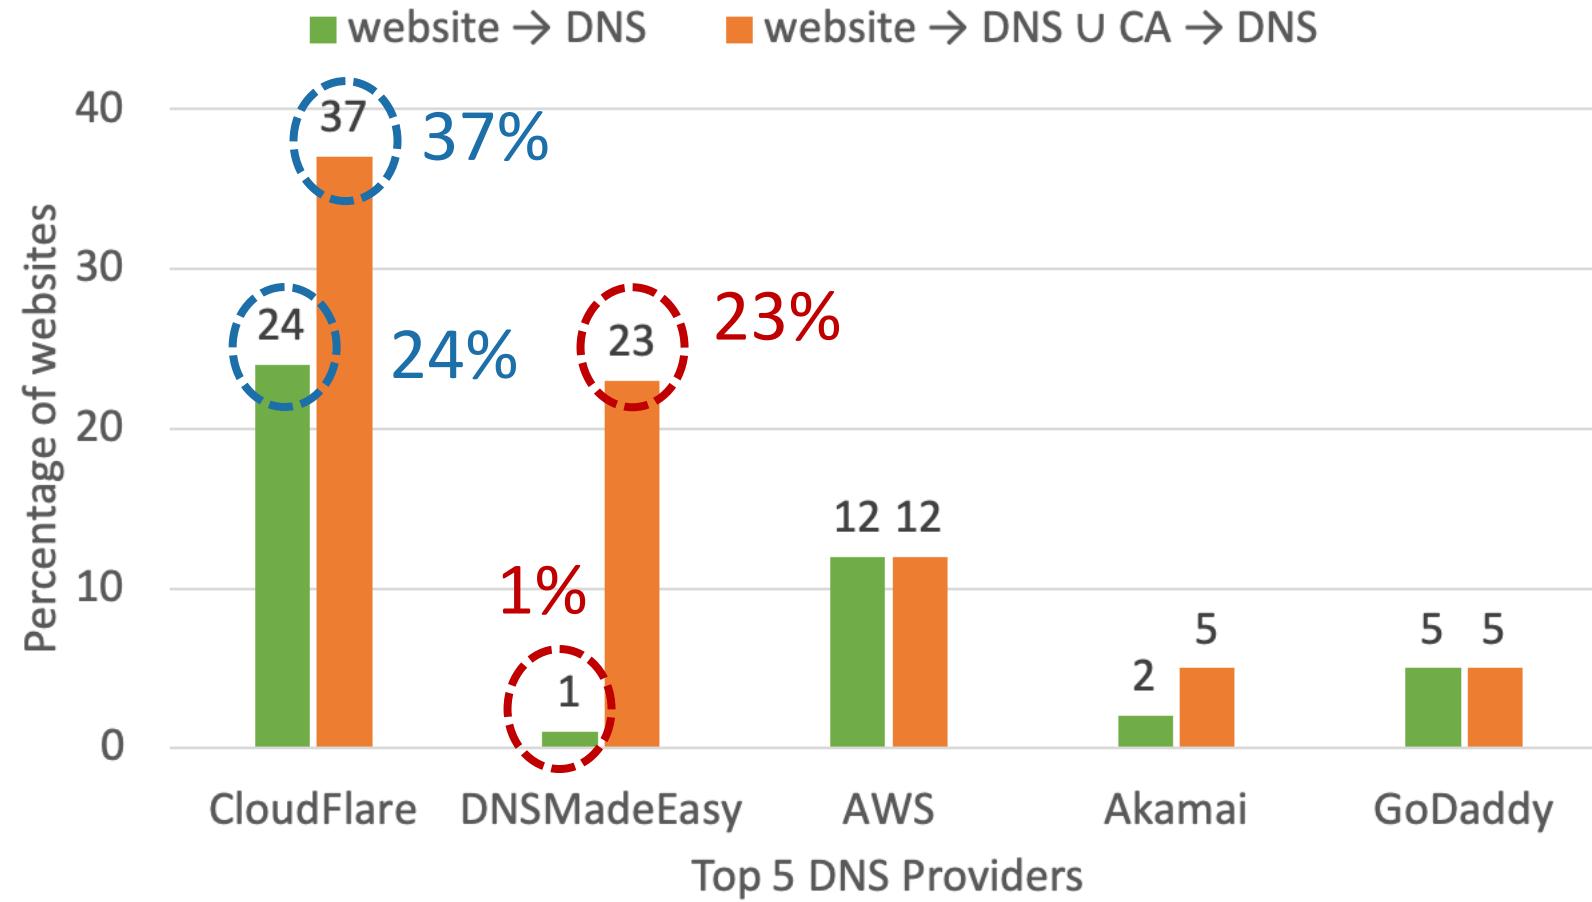

CA → CDN

17%

CDN → DNS

Due to inter-service **critical dependencies**, websites have indirect dependencies on service providers

Indirect Dependencies Amplify Concentration

Indirect Dependencies further amplify provider concentration

Takeaway

- Third party inter-service critical dependencies are also widespread
- Inter-service critical dependencies amplify the concentration of service providers

Implications:

- Single points of failure on the internet are amplified by inter-service dependencies
- A single service provider can impact 37% of the top 100K websites.

Q3: How did the world change
after the Dyn incident in 2016?

Critical Dependency of Websites (2016 to 2020)

+4.7%

0%

-0.2%

website → DNS

website → CDN

website → CA

No improvement in the prevalence of third-party dependency. Critical dependency increased in DNS

Inter-Service Critical Dependency (2016 to 2020)

-8.6%

CA → DNS

0%

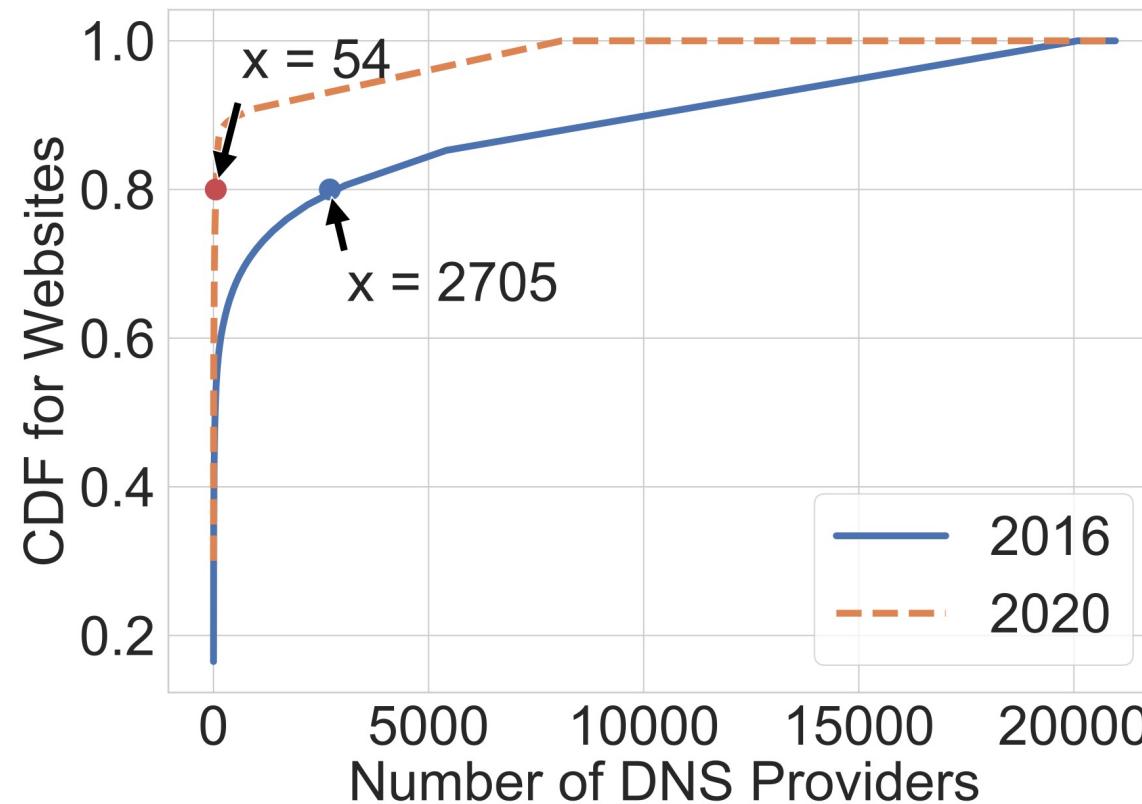

CA → CDN

-4.3%

CDN → DNS

Critical dependency decreased in service providers

Change in Concentration of DNS Providers

Single-points-of-failure got bigger in DNS and CA!

Takeaway

- No significant change in the prevalence of third-party critical dependencies in websites
- Inter-service critical dependencies on DNS decreased in 2020.
- Concentration of DNS and CA providers increased in 2020.

Implications:

- No increasing trend in redundancy.
- Single points of failure in the internet got bigger in 2020 vs. 2016

Outline

- Measurement Methodology
- Findings
- Recommendations
- Limitations
- Conclusion

Our Recommendations

Websites

- Redundancy when using third party providers
- Understand their indirect dependencies

Service Providers

- Support and encourage redundancy
- Be careful about their inter-service dependencies
- Be more transparent about attacks

Outline

- Measurement Methodology
- Findings
- Recommendations
- Limitations
- Conclusion

Limitations

- Measurements from a single vantage point
 - May miss region specific dependencies
- Analyze dependencies on landing pages only
 - May miss dependencies that manifest deeper
- Do not look at physical and network dependencies
 - For example, routing, hosting etc.

Conclusion

- DDoS attack on Dyn exposed the fragility of the Web due to dependencies
- Our work: Analyze third-party and inter-service dependencies
- Key Findings:
 - **Prevalence of third-party dependency:**
89% of top 100K websites are critically dependent
An attack on a single provider can take down ~30% of the websites
 - **Impact of indirect dependencies:**
~23X amplification in provider concentration
 - **Change after the Dyn Incident:**
No significant change in website dependencies
